The Argentinean debt: history, default and restructuring

Mario Damill, Roberto Frenkel and Martín Rapetti¹

1. Introduction and overview

We believe that the study of the Argentinean foreign debt needs no justification. For almost three decades, Argentina's foreign debt was continuously one of the main concerns of economic policy. Yet, both the record amount of the defaulted debt and the novel characteristics of its restructuring may be sufficient reasons to include an analysis of Argentina in a selection of studies about sovereign debt. Therefore, the processes that led to the default of the debt and its subsequent restructuring constitute one of the main focuses of this work. However, the Argentinean case also presents other aspects that demand attention, our analysis takes these into account as well.

The Argentinean experience is often used as an example of general arguments that take the country as a notable particular case. The rhetoric power of the example precisely comes from its supposedly well-known characteristics, yet sometimes these characteristics appear exempt of solid proofs. Many are second hand references and in some cases not even that but the mere mentioning of a "consensual image". Thus we are motivated to take a close look at what happened in Argentina.

This work is in part a polemic against some of those references that we consider fallacious. Each reference involves certain facts that we examine and try to explain. Our criticism also reaches the general plausibility of the argument that falsely takes the Argentinean case as an example. We think that the plausibility of an argument is strongly questioned when the argument is proved false in the case serving as its notable example.

1.1. Debt intolerance

First let us consider the argument that takes the Argentinean experience as an example of debt intolerance. Some economists include Argentina into the group of countries that carry the "original sin" of being serial defaulters and consequently suffer from debt intolerance (Reinhart, Rogoff and Savastano, 2003; and Reinhart and Rogoff, 2004). From this perspective, the general explanation of the recent crisis and default is due to two factors, the first being the country's own debt intolerance, an inherent characteristic attained by the country during its two centuries of existence. The second factor is the governments' irresponsible behavior, pushing the foreign debt above the country's low limit of intolerance. The diagnostic requires an international financial market willing to lend over that limit. The propensity to do so is considered an intrinsic feature of the financial markets, associated to its pro-cyclical character. In those circumstances, the high risk premium charged by the market and the propensity to sudden stops make their contributions

¹ Researchers at CEDES. This paper has been prepared for the project "Debt Restructuring and Sovereign Bankruptcy" of the Initiative for Policy Dialogue (IPD), Columbia University, New York. The authors thank the collaboration of Marcela Fraguas and Julia Frenkel.

to determine a high probability of default. Argentina's latest default adds to the series, confirming that the original sinners sin repeatedly.

A critique of this vision helps us to set some issues related to the problem of the Argentinean foreign debt in a long-term perspective. The first critique has to do with the irrelevance of the remote past. The insertion of the developing economies into the present phase of financial globalization dates from the beginning of the seventies, when the international banks plenty of liquidity were anxious to lend and Latin American countries became the first recipients of these credits. Which could be in this context the relevance of the memories of the thirties' international crisis? After forty years of practical inexistence of an international capital market, the countries' foreign debts were small and concentrated in governments and multilateral institutions.

In any case, had the remote past been relevant it would simply improved the risk valuation of Argentina, since in the thirties the country completely fulfilled its financial obligations whereas nine other Latin-American economies fell in default and an other four paid only part of the interests (US Department of Commerce, 1933). Argentina was the exceptional case among Latin-American debtors; it was the country that didn't fall in default in the thirties!

All the Latin-American economies that became indebted to the international banks in the seventies, including Argentina, fell in default in the 1981-82 crises (although Colombia restructured its foreign debts without defaulting).

If the remote past is irrelevant and all the indebted Latin-American economies fell in default in the early eighties, only the post crises countries' trajectories could explain the differences in risk valuations made by the international financial markets. Interestingly, although they came from a common experience of crisis and default, the countries' evolutions have taken different directions. Which are the most important elements differentiating the countries in the eyes of the international market: reputation or the debt-sustainability indicators?

Let us exemplify our view by considering the four biggest Latin-American debtors that fell in default in the beginning of the eighties: Argentina, Brazil, Chile and Mexico. All of them are classified as serial defaulters in the "debt intolerance" approach. Among these countries, only Argentina fell again of default later on. Certainly, Brazil and Mexico did suffer from "debt problems" after the crises of the early eighties (and also Argentina in 1995, when the country experienced the "Tequila effect" crisis), but they fulfill their external obligations.

The four mentioned Latin-American economies got different—and changing—country risk valuations from the market in the nineties. The countries followed different trade and financial integration paths that led to configurations with different degrees of vulnerability vis-à-vis the market's volatility and contagion that emerged in the nineties. We have argued in other works that those different paths—reflected in dissimilar evolutions of the debt ratios and other indicators of foreign debt sustainability—are to a great extent associated with the different policies followed by the countries from the second half of the eighties (Frenkel, 2003a and 2003b; Damill et.al., 1993). Certainly, fiscal and public debt policies played a significant role,

but the exchange rate policy and the financial opening management—intended to facilitate the preservation of competitive exchange rates—were also singularly relevant.

The extraordinary emphasis that the debt intolerance approach puts on both the remote past and rigid institutional features takes the focus away from what could be the most fruitful perspective in an international comparative analysis of the external debt problem: the different policies followed by the countries in their processes of financial integration into the global system. The four above-mentioned Latin-American economies well illustrate this point. They have a common remote past (with the caveat that Argentina did not fall in default in the thirties), a similar first phase of indebtedness in the seventies and the default in the beginning of the eighties. Nevertheless the debt ratios, the foreign debt sustainability indicators and the market's risk evaluations showed different evolutions in the nineties. An analysis of the differences in the recent past is clearly more interesting than the common features of the remote past.

In this work, our long-term analysis pays special attention to the economic policies that framed Argentina's external debt growth. We conclude that there is no supporting evidence for the "debt intolerance approach". We show that at the end of the seventies the country built up an intolerable debt burden. The origin of the external debt problem is not due to a remote "original sin" but to a more recent original policy mistake—essentially, the combination of capital account opening, fixed nominal exchange rate and appreciated real exchange rate. That original policy mistake was repeated again in the nineties.

1.2. Fiscal profligacy

The second argument we criticize is the one that takes the Argentinean case as an example of how uncontrolled public spending is the main cause of crisis and default. This is probably the most common, yet false, image of the Argentinean case (Mussa, 2002). We have analyzed this issue in previous works (Damill and Frenkel, 2003; and also Damill, Frenkel and Juvenal, 2003). The polemic leads us to a detailed examination of the fiscal accounts.

We show that the cumulative effects of the interest rates' rise, pushed by the increase in the country-risk premium due to contagion after the Asian and Russian crises, were the main cause of the public debt dynamics in the last quarter of the nineties. Interest rates in Argentina rose more than in many other countries in the region. The interests' item was the main factor explaining the increase in the fiscal deficit in the 1998-2001 period. The fiscal deficit increased despite a significant rise in the primary balance surplus.

The deficit of the pension system following the social security reform of 1994 also contributed to the increase in the fiscal deficit. The fall in the public pension system receipts mainly resulted from the recession and the employment contraction that started in mid-1998; thus, it was also an indirect effect of the new financial conditions.

The climbing trend in the country-risk premium and the interest rate can be associated with the situation of the fragile external accounts or, alternatively, with the evolution of public finances, or with both, as the investment funds analysts and the risk rating agencies actually did in their

reports. However, even if the uncertainties regarding public debt sustainability weighted significantly in the investors' assessments, this should not overshadow the original source of the rise in public deficits and debt in the late nineties. The main source was not an exogenous mistaken fiscal policy, but the compounded effects of inherent fragility and contagion.

1.3. The benefits and costs of default

In this work we also question the view that identifies the default as the main responsible factor for the deep Argentinean crisis in the early part of the twenty first century and its high social cost. Our analysis shows that the abrupt contraction in the activity and employment levels began, to a great extent, before the default, while the government submitted the country to big efforts to keep the debt services on track. The collapse of activity and employment was a consequence of the generalized run towards external assets and the liquidity crunch. And then in the first quarter of 2002, the real devaluation added another contractionary effect. Actually, the default turned out to be one of the conditions that enabled the recovery that took place soon after. This was not only due to the positive fiscal effect of the payments suspension, but also a consequence of having freed the economic policy from the need to continuously issue signals aimed at facilitating the roll over of the debt obligations. It allowed the implementation of a pragmatic macroeconomic policy, focused on the stabilization of the exchange market and the quick recovery of fiscal revenues, which became feasible when no further new private or multilateral external fresh funds were needed. The success of this policy provided the base for the recovery. Our conclusion is that when a country faces a crisis motivated by firm expectations of default, what is really costly is the postponement of the default and not the default itself.

1.4. Argentina, the IMF and the international financial architecture

The role played in the Argentinean case by the evolution of the international financial architecture is also a matter of interest. At first glance it is striking that the crisis and the massive default took place in a country that for a long time was considered an example of the Washington Consensus success. Almost until the end of the nineties, the IMF and most of the financial market's analysts considered Argentina as one of the successful cases of macroeconomic policy and structural reforms in the financial globalization context. In the middle of the crisis, the IMF's commitment to the convertibility regime—particularly, the rescue package granted to the country in the end of 2000 and extended in 2001—generated criticisms and conflicts within the institution. These issues motivated a special investigation by the Independent Evaluation Office (whose mandate only covered the convertibility regime period).

The relationship between Argentina and the IMF was peculiar in the period following the default. The debt restructuring took place in the context of a conflictive relationship between the IMF and the country. It was also a period in which the role played by the IMF in the financial international system was changing. The most unusual feature in this process was that the IMF did not participate in the design and management of the debt restructuring. Neither did the organism audit the government's financial projections that justify the sustainability of the proposal. These circumstances have no precedent in the international financial system that has been developing since the seventies. The importance of this novelty is highlighted both by the record dimension

of the restructured debt and by the unprecedented haircut, one of the highest in the debt restructuring history of the recent globalization period. Is this the antecedent of a new relationship between the IMF, the emergent-market countries and the markets?

The mentioned topics are treated below in four sections. First we examine the evolution of Argentinean foreign debt in the long run and the macroeconomic policies that contribute to explain it. What happened in the nineties deserves special attention. Then, section 3 is dedicated to the analysis of the macroeconomic performance before and after the recent crisis. Section 4 presents the evolution of the public sector's financial obligations after the default and describes the restructuring proposal. Finally, section 5 examines the relationships between Argentina and the IMF and its repercussions on the international financial architecture.

2. Financial opening and indebtedness in the recent phase of financial globalization

2.1. The Argentinean debt in the long term

Before the recent financial globalization process Argentina showed low and stable debt indicators. The foreign debt, public and private, was mostly owed to multilateral organizations and governments. It fluctuated in a range of 10% to 15% of GDP from the beginning of the sixties to the mid seventies, as can be seen in graph 1.

From the mid seventies on, the confluence of some factors gave birth to a new stage markedly different from the previous one. In first place, after the oil shock in 1973 the strong expansion of the euro market opened the way for Argentina's easy access to international credit. Meanwhile, a deep liberalizing financial reform was implemented in 1977 and was followed by the progressive dismantling of foreign exchange controls to capital account private flows in 1978-80. These changes would jointly operate to completely change the country links with the international financial markets.

Graph 1

As can be seen in the graph, the foreign debt/output ratio showed a rising trend between 1976 and 2000. The ratio measured with the PPP exchange rate grew approximately 3 percentage points of GDP per year in this period. The curve is more volatile when the ratio is measured at current exchange rates, with sharp rises in the beginning and end of the eighties as well as in 2002, and a strong fall in 1990-93. These jumps are due to the real exchange rate instability experienced in the period, as can be seen in graph 2.²

The total foreign debt/exports ratio, another standard debt indicator shown in graph 3, complements the mentioned evidence. It rose abruptly since 1977, especially between 1977 and

² Note that the debt ratio is defined as: $(d \cdot P^* E / y \cdot P)$, where d is the debt measured in real dollars, P^* is the international price level, E the nominal exchange rate, y the real GDP, and P the internal price level. Therefore, this ratio is affected by variations of the real exchange rate (EP^*/P) . *Ceteris paribus*, the real depreciation increases the debt ratio and the real appreciation reduces it.

1982, and never returned to the previous level. The 1976-2003 average much more than duplicates the level registered in the period ending in the mid seventies.

Graph 2

Graph 3

2.2. Three stages

Between the mid seventies and present times, three main stages can be distinguished in the debt evolution.

In the first stage, between 1977 and 1982, Argentina went through a phase of financial opening and accelerated indebtedness that ended up in massive capital flight, exchange rate crisis, devaluation and default. The second stage involved a long period of international credit rationing, between 1982—the Latin American's debt crisis year—and 1990. The third stage comprises the 1991-2001 period. As the first stage, it was also characterized by financial opening and accelerated indebtedness and exhibited again many of its features. This is the convertibility period, which would also end up in capital flight, exchange and financial crises, devaluation and default.

In what follows, we present the main stylized facts of the mentioned stages. As we indicated in the introduction, some of them are in conflict with the conventional interpretation of the Argentinean indebtedness process and crisis.

The first fact that deserves to be highlighted is the role played by the private sector in the generation of external financial obligations. In both stages of accelerated indebtedness this sector was initially the most dynamic one. As can be seen in graph 4, the government's proportion in total obligations declines between 1978 and 1980. Something similar can be appreciated in the period starting in 1991, although in this case the process would be longer. Despite the strong public external debt rise in the nineties, its participation in total debt declined by more than 20 percentage points during that period.

Graph 4

A second important element to take into account is the widespread interpretation that considers the fiscal disequilibrium as the main cause of the crises and the defaults that followed both phases of accelerated indebtedness. We think that this diagnosis lacks solid support. We will consider this issue below, when we focus our analysis on the nineties' performance.

A third relevant element for the understanding of the indebtedness process is that Argentina entered the financial liberalization in the seventies experiencing high inflation. The same happened in the beginning of the nineties. The opening of the capital account was in both phases adopted together with the launching of anti-inflationary programs (jointly with other liberalizing-reform measures in goods, capital and financial markets). In both cases, the key instrument of the

stabilization policy was the fixation of the nominal exchange rate instrumented as an anchor for the stabilization of the prices.³

A fourth fact relates to the macroeconomic dynamics that results from some of the factors already mentioned: the combination of a liquid external financial context and the stabilization policy based on the fixed exchange rate and the trade and financial opening.

The stabilization programs based on the exchange rate anchoring and financial opening tend to produce a cyclical dynamic (Frenkel, 1983; Taylor, 1998; and Frenkel, 2003a). The exchange rate fixation encourages private capital inflows induced by the difference between international and domestic interest rates. The aggregated demand expands while inflation declines, although the residual inflation causes the real exchange rate to appreciate. The current account worsens as a consequence of increasing net imports, this is caused by both the exchange rate appreciation and the demand expansion. The external financial needs rise and debt accumulates. In other words, the vulnerability of the economy to negative external financial shocks progressively increases. The domestic financial fragility increases as well. Exogenous shocks may trigger the reversion of the expansionary trend. The change in the trend can also be caused endogenously by a domestic financial crisis, as happened in Argentina at the beginning of the eighties. The failed stabilization attempt of the late seventies led to an internal financial crisis that started in early 1980 and developed along that year. Finally, the program collapsed in early 1981 leaving a heavy burden of external financial obligations.

Table 1 presents the changes in the debt/GDP ratio, and the factors explaining them: the changes in the amount of the debt in dollars and the variations in the real exchange rate and in the GDP. It can be seen that between 1975 and 1980 the debt ratio rose by more than 19 points of GDP, measured with the PPP exchange rate (it passed from 13.2% to 32.4%). The figures in the same table show that this result was hidden by the strong exchange rate appreciation, since the debt ratio calculated with the current exchange rate not only did not rise but fell in almost 4 points of GDP in that same period.

Table 1

In 1981, the exchange rate anchor stabilization policy was abandoned. A new phase followed, characterized by massive devaluations of the peso. These devaluations caused the foreign debt ratio measured in current dollars to reach a peak level close to 60% of GDP in 1982. The figures in table 1 show that the jump in the debt ratio at current prices between 1980 and 1982 (more than 44 GDP points) was to a great extent due to an increase of more than 200% in the real value of the dollar.

Nonetheless, the debt in dollars rose 37% between 1980 and 1982. An important factor behind this increment was the rise in the international interest rates that resulted from the policy carried on by the Federal Reserve since 1979.

³ We are referring to “la tablita”, a program of prefixed devaluations implemented from the end of 1978, and the convertibility regime that established the free convertibility of the peso to the dollar at a 1 to 1 parity.

An important jump in the public sector proportion in the country's foreign debt can also be observed in those years (graph 4). In 1981-82 the public sector ended up absorbing a considerable proportion of the private foreign debt, with the approval of the international banks. This to a great extent explains the jump in the participation of the public sector in total debt. It should also be stressed that no haircut provided relieve to the public debt in the early eighties default situation (it would only come late and in homeopathic doses with the Brady agreement in 1992-93, as stated below).

In the following period of international private credit rationing the debt measured with the PPP exchange rate kept on increasing, though at a slow pace. It increased the equivalent of 10 GDP points between 1982 and 1990 (table 1). The external obligations in dollars continued rising despite the lack of access to the international market (although at a much lower speed than in previous stages). The stagnant output trend also helps to explain the above mentioned rise.⁴

Later on, in the nineties, the debt's rate of growth accelerated again, especially from 1992. The Brady agreement did not provide significant relieve to the debt inherited from the mistaken policies of the late seventies. The achieved haircut was practically insignificant. The main favorable impact of the Brady agreement was on the banks' portfolios, since they could transform into bonds the defaulted credits, including the past due interests.⁵

During the 1990-2001 period, the foreign debt/GDP ratio, measured with the PPP exchange rate, rose almost 30 GDP points (table 1). This jump was completely due to the increase in the debt in dollars, which surpassed the accumulated GDP growth. However, it can be seen that the debt ratio measured with the current exchange rate barely rose, as a consequence of the important real appreciation that took place in the period.

2.3. The public debt in the nineties

We have seen that the total foreign debt, measured with the PPP exchange rate, increased by almost 30 points of GDP between 1990 and 2001. About 60% of that rise was generated by the private sector. The participation of the private sector was even more accentuated in the early nineties: it was responsible for approximately 70% of the increase in the external financial obligations between 1990 and 1995.

The public sector debt issuing was more significant in the second half of the decade, when the international financial conditions worsened. Besides, the placement of public debt in the domestic market started to play a more significant role in those years.

⁴ Although the access to voluntary international funding was closed, part of the interest flows accrued in the eighties were accumulated as new debt, i.e. as bank credit involuntary funding, and would end up being recognized and instrumented in bonds with the Brady agreement.

⁵ In 1992, before the agreement, the bonds in circulation were only 17% of total public debt, whereas in 1993 they had reached almost 65% of it. On the other hand, foreign currency denominated bonds represented less than 13% of the public debt in 1992, but approximately 57% in 1993. The total haircut provided by the agreement has been estimated in about 2.3 billion dollars, equivalent to about 4% of total outstanding public debt at the end of 1992 (Damill, Frenkel and Juvenal).

The following graph illustrates the public debt evolution in the period.

Graph 5

The series in the graph and the figures in tables 2 and 3 allow us to describe the main stylized facts of the Argentinean public sector indebtedness in the convertibility decade.

Table 2

Table 3

The analysis of the fiscal accounts allows us to distinguish three different periods in the nineties. In the first period, a sharp adjustment in the public accounts is observed. The average deficit, which in the eighties was about 7% of GDP, decreased to less than 1% of GDP in the 1991-94 period. As figures in table 2 show, this was mainly due to an improvement of 6 points of GDP in the national public sector balance result, from which 90% is explained by the primary balance result.

The year 1994 was a breakpoint in last decade for many reasons, and ushered in the second period. The social security reform that created the Private Pension Funds was then instrumented. One of the consequences of the reform was a considerable loss in the contributions to the public subsystem. At the same time, the expansion initiated in 1990 was then coming to an end: Argentina would go through the recession associated to the Tequila effect in 1995. And finally, the government took several measures aimed at compensating for some of the negative effects of the combination of commercial opening and exchange rate appreciation. It did that by lowering the tax burden on the tradable goods production sectors. All of the mentioned factors negatively affected the public finances. In spite of these negative effects, between 1995 and 1997 the average fiscal deficit was only 2 points of GDP higher than the early nineties deficit. This figure is almost equivalent to the increase in the public social security subsystem disequilibrium caused by the reform.

However, after 1997 the fiscal panorama would change significantly bringing us to the third period. The impact of the Russian and Brazilian crisis in 1998 resulted in a new jump in the country-risk premiums, which had already started rising since mid 1997, after the South East Asian crisis. This, on the one hand, negatively affected the internal demand and triggered a new recession trend. On the other hand, it increased the financial vulnerability of debtors, including the public sector as well as many private agents that were in a net debtor position.

Before analyzing this stage in more detail, let us take a look at the association between the fiscal results and the public debt evolution using the figures in table 3.

It is important to observe the discrepancy between the variation of public sector's financial obligations and the accumulated fiscal deficit, which represents more than 30 billion dollars in the nineties. The figures in table 3 show the main reason for this inconsistency, namely the

verification of debts incurred in previous periods but not registered in the fiscal results balance, especially debt with the public sector purveyors and with the social security system's beneficiaries (skeletons). There were erroneous liquidations and payment delays, mainly during the 1989-90 period, when the economy experienced two short hyperinflationary episodes.

The documentation of past debts was mostly concentrated in the initial stage, between 1991 and 1994. Although, it should be noted that the public debt ratio measured as percentage of GDP was relatively stable up to 1994, at around 30% in the case of total debt and 25% in the case of foreign debt (graph 5).

In comparison to the eighties, the 1991-94 phase was characterized by a significant improvement in the public accounts and by the relatively ordered absorption of a considerable volume of debt mostly generated in previous periods, i.e. by the regularization of liabilities, many of which were litigious. It is clear from these figures that the standard financial vulnerability indicators showed no evidence of fiscal sustainability problems in 1994, when the shock resulting from the Mexican crisis contagion reached the Argentinean economy.

However, it is undeniable that the high debt burden inherited from the previous phase—a sort of original fiscal sin of the nineties—is partially hidden by the real appreciation veil. Graph 5 shows the public debt/GDP ratio calculated with the PPP exchange rate. As it can be seen, the curve intersects the 50% line in 1993. The dollarization of the public debt establishes a direct link between the external fragility and the fiscal financial fragility, since taxes are paid in domestic currency. The relevance of this link is stressed by the exchange rate appreciation.

Between 1995 and 1997 the public debt/GDP ratio increased, in part as a result of the 1995 recession, and also because of the significant financial aid package led by the IMF, amounting to approximately 11 billion dollars. This support enabled the country to quickly recover from the crisis that followed the tequila effect. As seen in graph 5, in the expansionary phase that followed the crisis, the debt ratio tended to stabilize again between 35 and 40% of GDP, a relatively low level in comparison to international standards. Again, in spite of the rise in the current deficit and the disequilibrium in the social security system, the standard debt indicators did not suggest fiscal sustainability risk in 1997, before the beginning of the depression. However, the debt ratio measured with the PPP exchange rate had already reached 60% of GDP.

As pointed out above, Argentina's macroeconomic panorama would drastically change soon after, following the August 1998 Russian crisis.

Table 4 helps us to understand some key features of the fiscal evolution in this stage. The public sector's deficit increased significantly reaching about 6 points of GDP in 2001, despite the many rounds of contractive fiscal policies instrumented to stop the trend.

Table 4

In table 4 we compare the average disequilibrium of the depression period to the deficit registered in 1994.

In 1998-2001 the average accrued annual deficit (amounting 11.5 billion dollars) was 7.1 billion dollars higher than the deficit registered in 1994. What was the source of this increase? As far as it can be seen, it was chiefly due to the rise in the interest payments (+6.8 billions) and to the amplification of the social security system gap (+4.9 billions). Contrary to the standard interpretation, a relatively minor figure (+582 millions) is explained by the disequilibrium in the result of the provincial administrations, though it is true that it was on an increasing path.

The table also suggests that the pro-cyclical fiscal policies implemented were not ineffective: they produced a substantial increase in the primary surplus of a more than 5 billion dollar annual average (without including the public social security results), though that was not sufficient to compensate for the rises in the interests item and in the social security system disequilibrium.

The explosive trend in the public debt interests account is also observed in the following table.

Table 5

The weight of interests on tax resources, which slightly increased after 1994, takes a fast upward trend after 1996. In 2000, that ratio was nearly 19%, duplicating the ratio registered in the middle of the decade. This was in part due to the decrease in tax revenues caused by the recession, but it fundamentally originated in the rise in the average interest rate paid by the public debt. The average interest rate of the total public debt went from 5.8% in 1996 to 9.4% in 2001. Considering that this is an average rate, it is easy to see that the marginal rate rise was considerably higher.

The rising path of the interest rate is associated with the increasing trend in the country-risk premium (the two variables were narrowly correlated in the 1997-2001 period). These rising trends are the main factors behind both the consolidated deficit trajectory and the explosive path taken by the public debt. This is illustrated in graph 5. Between 1997 and 2001, in only four years, the public debt/GDP ratio increased by more than 20 percentage points.

3. The macroeconomic performance before and after the default

3.1. The nineties: from euphoria to depression

The basic plot of the macroeconomic story of the late nineties was quite simple. To start with, the negative financial turnaround in the foreign environment experienced in 1997-1998, after the South East Asian and Russian crises, found the Argentine economy with a significant and growing current account deficit, a considerably appreciated currency and a visible lack of policy instruments to deal with these problems, given the rigidities of the adopted macroeconomic rule. Not surprisingly, in these conditions the country-risk premium jumped upwards and the access to foreign funds became more and more problematic. As explained in the previous section, the subsequently increased interest burden had a negative impact on all borrowers, including the public sector.

Because of the fixed exchange rate policy, the government lacked other policy instruments. Restrictive fiscal policies had to bear with the main burden of the adjustment to the new situation. The Government's argument was that fiscal discipline would entail stronger confidence, and consequently the risk premium would fall, bringing interest rates down. As a result, domestic expenditure would recover pushing the economy out of the recession. Lower interest rates and an increased GDP would, in turn, reestablish a balanced budget, thus closing a virtuous circle. De la Rúa's administration borrowed this entire argument from Carlos Menem's administration and the IMF gave its seal of approval. All of them failed.

The entire macroeconomic story of the late nineties is about this failure. Despite the strong adjustment in the primary result of the public sector that we have already mentioned in the above section, the virtuous circle was never attained. Even worse, the increases in taxes and the cuts in public expenditures reinforced the recessionary trend, thus feeding the negative expectations that prevented the highly anticipated fall in the country-risk premium. Fiscal policy alone was impotent to compensate for the strong macroeconomic unbalances, which laid somewhere else, in the external sector of the economy. Under this self-destructive fiscal policy orientation, the economy got trapped into a vicious circle for several years, and suffered from the longer recession since the First World War.

3.2. The balance of payments and the public debt under the currency board

In the following graph we present the results of the principal accounts of the balance of payment in the nineties, acting as a complement to our previous discussion by illustrating some important aspects of the performance of the economy under the currency board regime.⁶

Graph 6

Let us start by making a short reference to the early nineties. The macroeconomic performance of the 1991-95 period clearly fit the stylized cycle described in the previous section. The capital inflows-led growth lasted until 1994. In early 1994 the Federal Reserve started to increase the discount rates affecting the capital inflows negatively and causing the foreign reserves to stop growing, due to the continuously increasing deficit in the current account.

Then, the contagion of the Mexican crisis of December 1994 triggered a massive capital outflow at the beginning of 1995, with a sharp increase in interest rates. Foreign reserves fell, as can be seen in Graph 6, and a contraction ensued. However, the recession of mid nineties was short-lived. As was already mentioned, a strong financial-support package structured with the coordination of the IMF helped to change the negative expectations.

Due to the favorable effects of the external financial support, it was possible to preserve the monetary regime and in late 1995 a new expansion was already starting. The elements of the cyclical dynamics were once again in motion. The expansion phase that followed showed the

⁶ A formal model of the dynamics of the Argentine economy under the currency board regime as well as its econometric estimation can be found in Damill, Frenkel and Maurizio (2002).

same stylized facts of the first, although this time it was shorter. The country-risk premium jumped in mid-1997, after the devaluation in Thailand. Then, after the Russian crisis of 1998, a new contraction started.

3.3. Foreign debt, public and private

Beyond the mentioned similarities, the second cycle of the nineties differed from the first one in many respects. We want to highlight one of them here, namely the dissimilar roles played by the public and private sectors in the generation of the capital inflows that fed the accumulation of reserves—a crucial variable under the currency board regime.

During the first economic expansion, in the early nineties, private inflows were predominant in spite of the fact that the privatization of the most important state-owned companies took place during that period. Capital inflows to the public sector became significant during the recession of 1995, thanks to the foreign financial-support package we have already mentioned. Since then, capital inflows to the public sector were kept at a high level until the end of the period. Thus, the second expansion in the nineties was bolstered mainly by capital inflows directed to the national government.⁷ Meanwhile, net capital inflows directed to the private sector recovered slowly and from mid-1998 on they stopped flowing in significant amounts. Actually, an abrupt outflow started in late 2000.

As Table 6 shows, the increase in the foreign public debt surpassed 35 billion dollars in this period. This amount is quite close to the increase in the foreign financial obligations of the non-financial private sector, which was above 32 billion dollars. If we add the increase in the external liabilities of the domestic financial sector, the amount jumps to more than 44 billion dollars, but with a significant fall in the critical period 2000:4-2001:4. Thus, the rise in the amount of the public foreign financial obligations (including the Central Bank) explains about 44% of the change in the total external debt during that period, or about 38% if the year 2001 is excluded from the calculation. The public sector played, as we have just stated, a crucial role in the financing of the accumulation of foreign reserves in the nineties. Certainly, the increase in the foreign debt of the private sector was no less important, but a significant portion of it had a counterpart in private outflows of funds. In effect, while the private debt experienced a considerable increase, also did the external assets of this sector. The Table 6 shows that foreign assets grew more than foreign liabilities in the case of the non-financial private sector. As we have analyzed in other works, this sector's net demand of foreign currency was positive in the aggregate (Damill, 2000; and Damill and Frenkel, 2003).

Table 6

⁷ Notice that the main channel was not the foreign financing of public expenditures, but a monetary mechanism: the issuing of new foreign debt by the government surpassed its payments in foreign currency. By selling this surplus to the Central Bank, the Treasury covered the net foreign currency needs of the private sector and fed the accumulation of reserves, essential for the expansion of both the money and credit supplies at the domestic level. The mechanism is discussed in Damill (2000).

The accumulation of foreign assets by the private sector was small in 1991-94. It rose during the second half of the decade, after the Tequila shock. As it can be seen in the table, in the expansionary phase extended from late 1995 to mid 1998, the private debt increased rapidly. It grew by more than 15 billion dollars (for the non-financial sector). But private foreign assets went up in a roughly similar amount.⁸ Furthermore, from then on the net private foreign debt declined substantially. In the whole period, it fell by about 19 billion dollars, according to the figures of the table. Synthetically, in the late nineties the level of reserves and the internal liquidity became more and more dependent on the access of the public sector to foreign funds.⁹

3.4. The efforts to prevent the default and the end of the currency board regime

As usually happens during a crisis, its development involved a complex succession of events, including many contradictory policy decisions (especially throughout 2001) and steps both backwards and forward. We will only mention here some crucial aspects of these processes.

In December 1999 a newly elected government took office. As we have already said, the new administration adhered to the belief that the main cause of the economic depression was not the exchange rate appreciation and the financial vulnerability to external shocks, but the fiscal mismanagement. This vision led the government to adopt a tight fiscal policy as a way to, quite paradoxically, take the economy out of the recession. We have presented these arguments and the expected results above.

However, the failure of this policy orientation should not hide the fact that huge efforts were made to balance the public accounts and to prevent the default of the government's financial obligations.

Indeed, aiming at reestablishing the bridges to the international financial markets, successive packages of tight fiscal measures were applied during 2000 and 2001, grounded on the fiscal consolidationist view of the crisis. We do not intend to describe them in detail here, but some episodes deserve to be mentioned as examples of the actions oriented to fulfill the commitments with creditors, both foreign and domestic.

The efforts to prevent the default included, among other measures, a Fiscal Responsibility Law approved in late 1999 that set a mandatory declining trend for the public deficit that should bring it to zero in a few years. Tax increases and expenditure cuts were adopted with that purpose. Later on, when the credit constraint had strengthened, a "zero deficit" policy was approved by mid 2001 determining that the public accounts had to be immediately balanced (so that total expenditures had to be adjusted to total cash receipts). The norm intended to guarantee some basic payments of the state, including interests on the public debt, and making endogenous the

⁸ Capital flights and the dollarization of private portfolios had also been a central feature of the crisis of the financial opening experience of the late seventies. Thus both policy experiments ended, among other aspects, in a strong denationalization of private wealth.

⁹ Note, in table 6, the important declination of the financial sector external assets in the crisis phase (that adds up to more than 10 billion dollars in 2001 alone). However, this is basically a reflection of the capital flight of the rest of the private sector. In effect, banks then held the main part of their reserves ('liquidity requirements') in liquid deposits abroad. Facing the withdrawal of deposits, the banks were forced to use those funds, hence their external assets declined while the external assets of the rest of the private sector increased.

rest of the expenditures subjected to the evolution of public receipts. The other “protected” items were legally established transfers of tax receipts to provinces, and wages and pensions amounting less than 500 pesos per month (or dollars at the ruling parity). The package included an unprecedented 13% across the board cut in public wages and pension benefits, which hardly contributed to either the social approval of the government policy or the social peace. It should be kept in mind that these measures were taken when the economy was already ending its third recession year. These decisions exemplify the huge efforts made to prevent a default on the public debt.

In any case, the expected "confidence shock" never materialized. With the economy suffering from a deep recession and caught into a debt trap, these rounds of contractionary fiscal policies only reinforced the deflationary scenario and the pessimistic expectations, as we have already explained.

During 2000 and 2001 the government attempted to complement its fiscal measures with some initiatives on the financial front. It obtained foreign support and implemented important debt swaps aiming to convince the public that there was no risk of default. Thus, at the end of 2000 an important package of local and external support, for about 40 billion dollars, was announced: (the “blindaje”, financial shield). The IMF led the operation with a 13.7 billion dollar extension of the stand-by credit in force since March 2000. Local agents including a group of banks and the private pension funds also had a significant participation. The beneficial effect of this action was very short lived. Two months after its announcement, and following the outburst of a new crisis in Turkey, the country-risk premium started to climb again.

Later in mid 2001, an important voluntary debt swap (the "mega-canje") was implemented to seduce private creditors (local and foreign). The transaction amounted to about 30 billion dollars in public bonds (24% of the total debt of the National Public Sector at the moment) and had the IMF's support. The operation made possible some extension in the duration, but involved an increase in the nominal debt (of about 2 billion dollars) as well as a heavy interest burden, because the newly issued bonds committed dollar interest rates of about 15%. Instead of alleviating the financial constraint, these high interest rates contributed to consolidate the perception that the debt path had become unsustainable.

Finally, there was another voluntary swap of public debt in November (although it would be better to call it “induced” or even, semi-voluntary). This was directed to domestic bondholders (mainly banks and the private pension funds), who agreed to swap more than 42 billion dollars in public bonds for the same amount in loans of lower yield insured by tax revenues. However, the operation could not stop the on-going divergent processes.

The withdrawal of bank deposits and the contraction of international reserves started in October 2000, with the resignation of Vice-President Alvarez. In March 2001, after the ephemeral recuperation that followed the announcement of the “blindaje”, this process became more intense and lasted until mid-June, when the government took a new measure aiming at changing the expectations: the “mega-canje” (mega swap). As we have mentioned, the stabilizing effects of this operation were very weak. In the beginning of July, the deposits withdrawal and the run

against the reserves started again. The intensification of these processes could neither be stopped with an announcement in August of a new extension of 8 billion dollars of the current IMF stand-by credit, nor with the debt swap in November.

Beginning in December the government established hard restrictions on capital movements and on cash retirements from banks (the so called “corralito”). One of the purposes of these measures was to avoid either the generalized bankruptcy of the banks or the violation of the currency board monetary rule. No bank, domestic or foreign owned, complained. But the main objective of the measures was to hold back the demand for foreign currency, preserve the stock of reserves and avoid the devaluation (i.e. the formal abandonment of the convertibility regime). It was also the last drastic move attempting to prevent the default. Yet, the measures actually did represent the end of the regime.

The December financial restrictive measures contributed to a deepening of the already strong social and political tensions. After a few days of social unrest and political commotion the country experienced the resign of the government followed by a series of ephemeral presidents. One of them announced to the Congress the decision of defaulting the public debt, only to resign a few days later. In the first days of 2002, with a new president, the economic policy officially abandoned the currency board regime and the one-to-one parity of the peso to the US dollar.

3.5. The macroeconomic performance after devaluation and default

After three years of recession, the economic activity suffered from an additional abrupt fall since mid-2001. The massive flight to external assets that took place in the second semester precipitated the collapse of the convertibility regime and resulted in the devaluation of the peso and the default. Graph 6 shows the strong fall in reserves experienced along that year that rapidly shrank the liquidity. The payments chain collapsed after the “corralito” was established. The output and employment followed the abrupt contractive trajectory showed by the reserves and liquidity. Social indicators such as the unemployment rates and the poverty and indigence indexes—which had considerably worsened during the nineties—suffered from an additional deterioration, adding to the social tensions and the politic crisis that brought the government of the Alianza to an end (Damill, Frenkel y Maurizio, 2003).

3.5.1. The economic recovery

The abyssal fall in output and employment continued after the end of the convertibility regime, but for only a very short period. Certainly, in opposition to most opinions and beliefs—including those of the IMF’s officials—the traumatic episodes that brought the convertibility regime to an end were not followed by a deeper depression. Moreover, an extraordinary quick recovery started only one quarter after the devaluation and default, as can be seen in graph 7.

In the graph, the “V-shaped” trajectory can be seen consisting of the economic collapse phase of the last quarters of the convertibility regime and the following quick recovery. As we have just indicated, the GDP recovery started soon after the exchange rate depreciation (around three months later, as can be seen in the available monthly activity indicators). The recovery was

precisely triggered by the sudden change in the relative prices in favor of the tradable goods sectors. In the beginning of this phase the recovery was led by the local production of previously imported goods.

Graph 7

It is remarkable that the beginning of this new phase started to be perceptible while the country was still immersed in a context of accentuated economic still instability and political uncertainty, and when the services payments of part of the public debt were interrupted.¹⁰ In other words, the “rebound” took place in spite of this extremely complicated setting and also despite the short-term recessionary effects of the depreciation.

3.5.2. Despite the IMF

Apart from the shift in the relative prices, the quick economic recovery that followed the crisis is also a consequence of a set of policies that, still with flaws and ambiguities, aimed at recovering the basic macroeconomic equilibria.

We discuss the Argentinean relations with the IMF in greater detail below in section 5. However, for the purpose of this section it should be stressed that many of the policies that played important roles in this stage faced opposition from the IMF. Firstly, the imposition of exchange controls. This measure compelled the exporters to liquidate in the local market a considerable part of the international currency generated by the exports and also restricted the capital outflows. Secondly, the establishment of taxes on exports (retentions), which absorbed part of the devaluation’s favorable effect on the exporters’ incomes (thus significantly contributing to the recovery of the fiscal equilibrium), and attenuated the impact of the devaluation on domestic prices and, consequently, on real wages. Thirdly, a flexible monetary policy that initially enabled assistance to banks in the crisis phase and afterwards contributed to the recovery of the money demand, thus helping the recovery. Fourthly, when the exchange market started to show an excess supply of international currency, an exchange rate policy attempted to avoid the peso appreciation throughout the interventions of the Central Bank (and of the Treasury later on).

The IMF particularly stressed their insistence on the free flotation of the peso. For a short period the government adopted this regime. Once the exchange rate was free to float the parity rose abruptly, reaching levels close to 4 pesos per dollar. The following reintroduction of exchange controls was crucial to contain the exchange rate bubble. The government managed to stabilize the nominal exchange rate by mid-2002 by compelling the exporters to liquidate the international currency in the local exchange market and by limiting the currency outflows.

Graph 8

¹⁰ When the floating regime was adopted, soon after the initial devaluation that had taken the parity to 1.40 pesos per dollar, the exchange rate was weakening; the depreciations pushed up the nominal prices, and the financial system was going through a deep crisis, etc.

Soon after, when the exchange rate was stabilized the demand for pesos started to recover and the exchange market began to show an excess of supply of dollars. The end of the exchange rate bubble put a check on the rise in the domestic prices. The freezing of the public utilities rates¹¹ as well as the high unemployment rates—that kept constant the nominal wages—also contributed to stop the rise in prices. The quick decline of inflation in the second half of 2002 can be seen in the graph 8.

Another important point involving the tense relations of the country with the IMF refers to the net flows of funds between Argentina and the multilateral organizations. In this regard, a substantial change can be seen after the end of the convertibility regime. Actually, in the post default phase the net funding of the IMF and the multilateral organizations became negative. According to the Argentinean Minister of the Economy the IMF passed from playing the role of ‘last-resort lender’ to play the role of ‘privileged debt payments collector’. This point is illustrated in the following graph.

Graph 9

Whereas in the 1994-2001 period Argentina received from the multilateral organizations a net funding of more than 23 billion dollars (40% of which were concentrated in 2001), in the 2002-2005 phase the country made net payments amounting more than 14 billions dollars (including interest payments).

In 2005 the government of President Kirchner decided to cancel the whole outstanding liabilities with the IMF, and that explains the significant size of the negative bar attributed to 2006 in the graph.

3.5.3. The main characteristics of the recuperation phase

The GDP recovery that started in the first half of 2002 had a short first phase in which the aggregate demand barely rose and in which every internal component of domestic expenditure (private consumption, public consumption, investment) kept shrinking, as it happened, though at a low pace, along the previous depression. Therefore, it was not the aggregate demand what stopped the declination in the activity level. The expansive factors were mainly the international trade variables, exports and imports—most especially the latter. The local production started to provide an increasing proportion of the aggregate demand. This imports substitution particularly favored the manufacturing sector. After that short initial stage, the activity level recovery was led by the increase in the domestic demand components, especially by the investment—that grew at an annualized rate close to 40% between 2002 and 2004—and by the private consumption.

It is frequently mentioned that the favorable external context was an important element behind the economic recovery. The main part of the rebound is often attributed to a set of positive “exogenous” factors. In those interpretations, the recovery would have taken place in spite of what is often considered an economic policy full of mistakes and omissions. Although the

¹¹ Many of which were dollarized and subject to automatic adjustment with the US rate of inflation, as established in the privatizations’ contracts.

contribution of external facts to recovery has been undeniable (in particular some commodities' high prices) the fact that the substantial part of the expansion's dynamism derives from internal demand sources weakens that interpretation.

It should also be stressed that the consumption and investment recovery took place in a context of accentuated credit rationing, both external and internal. The investment was apparently financed by higher profits retained by firms, although the "wealth effect" resulting from the significant external assets holdings of the private resident sector, surely contributed as well. These assets—that nowadays surpass 130 billion dollars—increased their value in pesos with the exchange depreciation, and also rose in relation to the prices of domestic assets such as real estate and land. This factor also fed the recovery of the private consumption expenditure.

3.5.4. Fiscal and external adjustment

The adjustment experienced by the Argentinean external sector in recent years took place to a great extent before the devaluation, as showed in graph 6 where the improvement in the current account since 1998 can be seen.

Actually, the abrupt contraction that characterized the end of the convertibility generated an important trade surplus. The trade balance exhibited a deficit higher than 3 billion dollars in 1998. It rapidly decreased from then on and turned into surplus, due to the reduction in the volume of imports. In 2002 the balance was higher than 17 billion dollars, and remained over 16 billion in 2003 (and over 12 billion in 2004). The trade surplus caused the change of sign in the current account balance. In recent years it has shown positive results even when taking into account the interests accrued by the debt in default (see graph 6). In fact, the macroeconomic policy has recently faced the problem of sustaining the real exchange parity in order to preserve the incentives to investment in the tradable goods sector within the context of international currency excess supply.

As can be seen in table 7, a strong adjustment in the public accounts has also been taking place together with the external adjustment process we have just mentioned.

Table 7

The improvement in the Consolidated Public Sector global result that took place between 2001 and 2004 was equivalent to 10 points of GDP. This result passed from a global deficit of 5.6% of GDP in 2001 to a 4.5% surplus in 2004.

Which factors explain the adjustment in the fiscal cash flow results? 40% of it derives from an improvement in the provinces' balances. This improvement comes from the increase in tax collection facilitated by the recovery and the rise in nominal prices, together with the restraint in expenditure. Meanwhile, 60% of the six-points-adjustment in the national public sector's budget is explained by the improvement in the primary result (+3.7% of GDP). The contraction of interest payments, basically resulting from the default of the sovereign debt, accounts for the rest (-2.4% of GDP).

The rise in the national primary surplus is mainly explained by an improvement in tax revenues (+4.7% of GDP). It is interesting to observe that although the receipts from traditional taxes such as the VAT and the Incomes tax rose significantly, they did not increase substantially when measured as a proportion of GDP. Between 2001 and 2004 they increased in 1.2% of GDP as a whole. The tax on exports is the item that mostly explains the rise in tax revenues. The soy and derivatives industry generated almost one half of the taxes on exports.

Hence, the public sector absorbed part of the effect of the devaluation on the profitability of the tradable goods sector, and also benefited by the high prices reached by some of the exportable goods, such as soy and oil. The contribution made by the tax on financial operations established in 2001 was also very relevant. The increase in the collection of this tax explains 30% of the improvement in total tax receipts.

The interest payments on the public debt deserve a separate paragraph. As can be seen in table 7, this flow passed from representing almost 4% of GDP in 2001 to only 1.4% in 2004 (without taking into account the accrued interests on the debt in default. Table 7 shows cash flows figures, not accrued flows).

However, the fiscal effects of the suspension of part of the debt services payments are significantly higher than what is shown in the mentioned account. It cannot be calculated with precision because a significant amount of new debt was issued after the suspension of debt payments, as we will describe in the following section. However it can be estimated that the amount of interests on the public debt—valued at the 2004 exchange rate—would have represented, in that year, between 9 and 11 points of GDP. This is approximately equivalent to one half of the total tax collection of that year. These payments would have certainly been incompatible with the economic recovery. As it was pointed out above, a crucial aspect of the fiscal financial vulnerability derived from the extremely high proportion of debt in foreign currency, with the consequent exposure to the impacts of the exchange rate variations. The 2002 substantial exchange rate depreciation would have had a harsh impact on the public sector's financial equilibrium. Taking this into account, it can be said that the payment suspension and the following debt restructuring enabled a considerable amount of fiscal savings—either measured in domestic currency or as a proportion of GDP.

However, the most important effect of the default and the end of the convertibility regime was the recuperation of the instruments of macroeconomic policy which was of crucial importance in moving the economy out of the abyssal situation generated by the agony and the final collapse of the convertibility regime.

4. The evolution of the debt after the default and the restructuring proposals

The suspension of the services payments of a part of the public debt was declared on December 24th of 2001 (by then the debt reached 144.5 billion dollars). The measure initially affected 61.8 billion dollars in public bonds and other 8 billion dollars in diverse liabilities. The rest –mainly

debt with multilateral organizations (32.4 billion dollars) and the recently issued guaranteed loans (42.3 billion dollars)—remained as performing debt.¹²

The devaluation of the peso that followed had a strong impact on the economy's contractual structure, given the important dollarization of contracts inherited from the convertibility period. A few days after the devaluation, in order to attenuate some of the consequences of the shock, the authorities resorted to the issuing of new debt. In this section we examine both the generation of these new liabilities ("non voluntary" and "inertial", as called in the official documents) and the restructuring process of the defaulted liabilities.

4.1. The evolution of public debt after the default

As it was pointed out above, there were government interventions aimed both at reducing the wealth transfer from debtors to creditors and at avoiding the collapse that would have resulted from the fulfilling of contracts set in foreign currency. The official intervention was intended at managing the "distribution of losses". In many cases the intervention meant that part of the losses were absorbed by the State by issuing new debt. The evolution of public debt in the period following the default is summarized in table 8 presented in the annex.

The main source of the new indebtedness came from the intervention in the financial system, which involved a 14.4 billion dollar public debt rise. In February 2002 the government decided to compulsively convert the foreign-currency bank deposits into pesos at a rate of 1.4 pesos per dollar.¹³ The withdrawal of the demand and saving deposits was restrained to 1,500 pesos per week. The rest of the deposits constituted until the end of 2001 was transformed in longer term deposits. This measure included both the deposits recently converted from dollars to pesos and those originally denominated in pesos.

Bank credits in foreign currency were converted into pesos at a rate of one peso per dollar. This measure was aimed at avoiding generalized bankruptcies in the private sector. The "asymmetric pesoification" of credits and deposits caused a significant loss in banks' net worth that was compensated by the government. The issuing of new debt with this purpose amounted to 5.9 billion dollars.¹⁴

¹² Let us remember that the November 2001 public debt swap mentioned in the previous section involved the swap of local agents' bond holdings for guaranteed loans to the government.

¹³ When the measure was sanctioned, the dollar was floating around 2.15 pesos. Four months later, the dollar exchange rate almost reached 4 pesos, and from then on it followed a smooth descendant path. From March 2003 on the parity tended to stabilize between 2.8 and 3 pesos per dollar.

¹⁴ Another measure with 'asymmetric' effects also affected the banks' net worth. The government established different inflation adjusting mechanisms of deposits and pesoified credits. It was resolved that the deposits would be indexed with an index that follows the consumer prices' evolution (CER) and that the loans would do so with another index reflecting the evolution of the average wages (CVS). Since the consumer prices inflation was higher than the nominal rise in wages, the value of the banks' pesoified liabilities grew at a higher rate than the value of the assets. In October 2003 the Congress sanctioned a law that empowered the government to compensate the banks for the 'asymmetric indexation' by issuing new bonds (BODEN 2013) for up to 2.8 billion pesos. Up to now, the government has not issued those bonds.

Many banks' financial positions in domestic and international currency were not hedged at the time of the devaluation. Therefore, the peso devaluation caused an additional loss in the banks' net worth. The government compensated this effect by issuing 2.4 billion dollar bonds ('bonos cobertura') denominated in foreign currency in exchange for banks' liabilities with the State.¹⁵

The pesoification of the private deposits at 1.4 pesos per dollar and the forced reprogramming of their maturities triggered strong claims. The savers claimed for the value of their deposits in their original currency denomination and for their free availability. In many cases there were judicial decisions favorable to these claims causing a considerable "filtration" of funds out of the banks. To tackle this situation, the government of President Duhalde launched three different proposals for the voluntary swap of reprogrammed deposits for new public bonds.¹⁶ The first two offers involved the swapping of the banks' debts with the savers for public debt. The third one was intended to free all the reprogrammed funds. In this case the government issued debt papers for the difference between the deposits' value in its original currency (dollar) and the amount effectively disbursed by the bank (1.4 pesos per dollar plus the inflation adjustment, following the CER index).¹⁷ The three offers as a whole reached a broad acceptance from the savers. This helped to alleviate the financial system's liquidity problem, though at the expense of augmenting the public debt in 6.1 billion dollars in exchange for banks debt with the State.¹⁸

Another source of the public debt increase came from the transfer of liabilities from the provincial governments to the central government. The latter absorbed 9.7 billion dollars of the provincial governments' debts with the banks. It also undertook the loss derived from the rescue of provincial governments' bonds that had performed as currency ('cuasi monedas') between 2001 and 2003.¹⁹ In this case, the national government assumed a liability of 2.4 billion dollars with the Central Bank, the institution that was in charge of the rescue of the provincial governments' bonds by issuing notes in exchange for the provincial bonds. Both transactions were granted by a proportion of the future flow of national tax resources distributed among the provincial governments.

During 2002 and 2003 the public debt also rose due to the accounting of obligations with employees, pensioners and purveyors for 2 billion dollars. A ruling of the Supreme Court—stating that the 13% cut applied to public wages and pensions since July 2001 was unconstitutional—forced the government to issue debt papers for 873 million dollars. Yet at the same time, the liabilities with purveyors and other debts committed before the default amounted 1.2 billion dollars. All together, the measures aimed at managing directly or indirectly some of

¹⁵ The banks were allowed to cover those obligations by depositing funds in the Central Bank or canceling debt that the State previously held with them.

¹⁶ The first offer was launched when the Minister Lavagna assumed in June 2002, the second one in September of the same year and the last one in March 2003, two months before the provisional mandate of President Duhalde expired.

¹⁷ The frozen demand deposits ('corralito') had already been freed in December 2002.

¹⁸ The covering mechanism was the same as the one established for the 'bonos cobertura'.

¹⁹ Since the second half of 2001 some of the provincial governments issued bonds that performed as money. When the rescue process started in May 2003, the total stock of "cuasi-monedas" had reached 7.5 billion pesos (2% of GDP).

the consequences of the convertibility collapse entailed a gross debt emission of 28.5 billion dollars.

In February 2002 the government determined the conversion into pesos of all the debt issued in foreign currency under the Argentinean legislation. The measure would affect the 57.5 billion dollar debt, most of it constituted by “guaranteed loans” issued after the November 2001 debt swap.²⁰ The government also decided to apply fixed interest rates to the “new” pesoified debt that varied from 2% to 5.5%. The “guaranteed loans” had been issued with a clause that allowed the holder to turn the asset into the original bond in case the original emission conditions were changed. In 2003 most of the private pension funds (AFJP) and the local insurance firms decided to re-convert their holdings of 17.8 billion dollars of “guaranteed loans” into the original foreign-currency—denominated bonds. In spite of that, the pesoification of the “guaranteed loans” reduced the value in dollars of the debt issued under local legislation by about 22.1 billion dollars.

However, the pesoified debt indexed with the CER experienced a rise due to the inflation. The same thing happened with the new bonds in pesos, issued to manage the losses caused by the exit from the convertibility regime. Until the end of 2003 the value of all these obligations rose due to the indexation effects of about 7.3 billion dollars. In a similar way, capitalized past due interests of the defaulted debt accumulated 13.9 billion dollars.

In summary, considering the different measures and effects derived from the management of the convertibility collapse and the declaration of default, between December 2001 and December 2003 the gross public debt stock increased by about 28.2 billion dollars.²¹

²⁰ The measure also affected public bonds (Bontes, Bocones, Bonos-Pagaré and Letes), bilateral loans, debt with commercial banks and other obligations that added up to about 15 billion dollars in that moment.

²¹ This calculation also includes the effect of the conversion into dollars of the 2008 bond in pesos, issued in June 2001 with the “mega-canje” (477 million dollars). It should also be mentioned that the financial assets of the national government (assets against the financial system and provincial governments) increased by about 11.1 billion dollars between 2001 and 2003, mainly due to the reasons mentioned above.

4.2. The proposals for the public debt swap

In the second half of 2003 the first official steps for the restructuring of the defaulted debt were taken. In September, after reaching an agreement with the IMF, the government took advantage of the annual meeting of the IMF and the World Bank in Dubai to make public the main guidelines and the agenda of their restructuring proposal.

The “Dubai proposal” established that the offer would be directed with uniform treatment to every bondholder of bonds issued until December 2001, while still performing the rest of the debt.^{22 23}

The government recognized a defaulted debt stock of about 87 billion dollars. This amount left aside an important volume of past due interests. A 75% haircut was imposed to this amount. According to those guidelines the issuing of new bonds would reach a maximum amount of about 21.8 billion dollars. The issuing of three bonds called Par, cuasi-Par and Discount was announced. Although the specific characteristics of the instruments were not divulged, it was mentioned that the Par would preserve the nominal value of the original debt but would have longer maturity and lower interest rate than the other two. The other two bonds would imply nominal haircuts. The haircut corresponding to the Discount bond would be higher than the haircut of the cuasi-Par. The new bonds would also incorporate mechanisms—which would be specified later on—to reward the bondholders with a coupon tied to the economic rate of growth. The sustainability of the proposal was consistent with the primary surplus that had been recently agreed upon with the IMF (2.4% of GDP for the central government and 3% for the consolidated public sector). The government announced that it expected to maintain that target in the long run.

The voices of the financial market expressed strong disapproval. It was affirmed that Argentina was in a position to make a much better offer by compromising a higher fiscal effort. The IMF exerted pressures on the government in many ways and repeatedly called for signs of “good-faith”. In June 2004, a few months after the G-7 finance ministers manifested that Argentina should accelerate the restructuring process and issue “good faith” signals, the government made public a new proposal in Buenos Aires.

Although efforts were made to present the “Buenos Aires proposal” as a refined version of the Dubai proposal, it was in effect a second offer that aimed to get closer to the creditors’ positions. The eligible debt was the same as the one defined in Dubai. The debt to be restructured amounted to 81.8 billion dollars.²⁴ In exchange for that defaulted debt stock new bonds would be

²² This set of obligations was denominated the ‘eligible debt’. It consisted of 158 instruments, issued in 7 different currencies (Argentinean peso, inflation-adjusted Argentinean peso, US dollar, euro, yen, sterling pound and Swiss franc) and 8 jurisdictions (Argentina, United States, Great Britain, Japan, Germany, Italy, Spain and Switzerland).

²³ Rigorously, a set of defaulted obligations (bilateral debt, debt with commercial banks and other creditors) remained without definitions regarding its restructuring. This set amounted about 7.5 billion dollars in December 2003 (including capital and past due interests). By the time this work is written, the situation of this debt was still unknown.

²⁴ In the Buenos Aires offer some details were specified that were originally omitted in the Dubai proposal. It was clarified that the ‘eligible amount’ was comprised of the value of the stock of bonds current at December 31, 2001 plus accrued interests up to that date. The difference between the resulting amount and the 87 billion dollar debt

issued for a total of 38.5 billion dollars, in case the level of acceptance of the swap was lower than 70%, and for 41.8 billion dollars in case the level of acceptance was higher than the 70% benchmark. This offer involved a substantial improvement if compared to the 21.8 billion dollars to be issued according to the Dubai proposal. In spite of it, the government manifested that the 75% haircut on the debt's nominal value presented in Dubai would be maintained, although the past due interests would now be recognized.²⁵ The announcement created confusion, since it was interpreted that the swap would consist of a new issuing of 38.5 or 42.3 billion dollars (according to the degree of acceptance) in exchange for an eligible debt that, in the Buenos Aires proposal, included the accrued interests amounting to 99.9 billion dollars (or 103.2 billion dollars, according to the degree of acceptance). As time passed, it was made clear that the swap would comprise only the capital of the defaulted bonds while the past due interests would not be recognized; i.e. liabilities amounting to 81.8 billion dollars would be exchanged for new bonds amounting to 38.5 or 41.8 billion dollars, depending on the level of acceptance.

The three instruments announced in Dubai were maintained in the Buenos Aires proposal: the Par, the cuasi-Par and the Discount.²⁶ It was established that the issuing date would be December 31, 2003 and that the bonds would accrue interests since then.²⁷ The offer to include a coupon tied to the GDP growth was also maintained. It was announced that the Par and Discount bonds could be issued in CER-adjusted pesos, US dollars, euros and yens. The cuasi-Par bond was exclusively issued in CER-adjusted pesos.

The offer specified a Par bond issuing of 10 billion dollars in case the acceptance was not higher than 70% and of 15 billion dollars in the opposite case. This instrument would recognize the original nominal value of the defaulted bond, would have a 35-year maturity and would have fixed rates (in dollars) rising from 1.33% during the first 5 years to 5.25% in the last 10 years.

For the Discount bond, an issuing was announced of approximately 20.17 billion dollars in the lowest acceptance scenario and of about 19.87 billion dollars in the most optimistic one. The new bond would imply a 66.3% haircut on the original nominal debt value, would have a 30-year maturity and would yield an increasing fixed interest, part of which would be capitalized throughout the first 10 years.

The cuasi-Par bond was designed to take into account the local institutional holders' needs—mainly the private pension funds—and involved a 30.1% haircut. The announced issuing amount was about 24.3 billion pesos (about 8.33 billion dollars) independently of the degree acceptance. The instrument would have a 42-year maturity, yielding a fixed 3.31% interest rate in pesos, with capitalization of interests during the first 15 years.

announced in Dubai was mainly due to different exchange rates used to convert into dollars the debt in other currencies.

²⁵ In the lowest acceptance scenario, the recognition of past due interests would include the period until December 31, 2003 for about 18.1 billion dollars, whether in the highest acceptance case, it would include the past due interests June 30, 2004, for 21.4 billion dollars.

²⁶ A detailed description of the bonds is presented in table 9, in the annex.

²⁷ This issuing date enabled interest payments immediately after the closing of the swap. This plan aimed at including a sweetener in the proposal as incentive for bondholders' participation.

The announcement made in June also specified the characteristics of the coupons tied to the GDP growth.²⁸ A quantity of unities would be issued equal to the amount of the capital effectively swapped. These unities could be separated from the bond and quoted independently 6 months after the swap. The possession of each unity would entitle the collection of the correspondent proportion of 5% of the observed GDP surplus over the “base GDP”, provided that the former had grown more than 3% in the previous year. The “base GDP” was defined as a GDP trajectory with a 3% average annual growth rate, using the GDP of 2004 as a starting point.²⁹

In comparison to the Dubai proposal, the improvement involved a higher fiscal effort in the future. The government announced that in order to guarantee the offer’s financial consistency it was committed to maintaining a 2.7 points of GDP primary surplus target during the first 5 years—when the service of the post default issued debt is concentrated—and stabilizing the primary surplus at around 2.3% of GDP from 2014 on. With this program and a 3.3% annual average growth assumption, the projections indicated that the fiscal effort would finance the interest payments, though it left aside a relevant proportion of the capital maturities, for which funding sources had to be obtained. Even if the multilateral organizations agreed to the refinancing of their debt amortizations, the government would still have to obtain annual funding for about 2% of GDP to face capital payments maturing along the first 10 years after the swap.³⁰

The evidence that Argentina would continue supporting a heavy debt burden after the swap did not ease the creditors’ demands. Immediately after the announcement in June, the bondholder’s organizations rejected the proposal, claiming that the country should pay more than what was offered. The financial analyses showed that the new offered debt value, including the coupons tied to the GDP-growth, was between 20 and 27-dollar cents. This signified a present value haircut of about 73% to 80%, which was considered unacceptable by the market’s participants. The discount rate used in these calculations was crucial. Most of the analysts considered it reasonable to use the yield of assets of similar-risk emerging market countries, which at that moment was around 12-14%.³¹

By late 2004 the international capital markets evolution unexpectedly started to play in favor of the Argentinean offer. The world liquidity stimulated the appetite for risk, which turned into an increasing demand from emerging markets debt and into a reduction of the developing countries’ risk premium.³² In this new context, the swap looked more attractive. The present value of the

²⁸ Table 10 shows a detailed description of its characteristics.

²⁹ Specifically, the planned “base GDP” trajectory establishes an initial 4.3% growth rate in 2005, decreases to 3% in 2015 and remains at this pace until 2034.

³⁰ The financial program would be even more demanding if the debt service to the multilateral institutions was included. In that case the government should get an average funding of 4 points of GDP per year along the same period.

³¹ Brazil’s debt was commonly used as a benchmark. Its yield then oscillated around 12%. The debt of Ecuador, a country that had recently restructured its external liabilities, yielded a rate close to 14%. High yields were a consequence of the unfavorable funding conditions that the developing countries faced at that time. The JP Morgan EMBI+ index, which measures the emergent market risk weight average, showed an average value of 502 basic points in May-June. In the same period Brazil’s country risk-premium averaged 691 basic points.

³² The EMBI+ index decreased to an average of 375 basic points in the last quarter of the year, whereas the Brazilian country risk-premium fell down to 417 basic points. The yield of Brazilian debt was about 9-10% and the yield of Ecuador bonds was about 11-12%.

offered bonds calculated with the discount rate settled by the new financial conditions (for instance 10%, the Brazilian debt yield) was between 30 and 35-dollar cents. This present value represented a 65-70% haircut and was similar to the market price of the defaulted bonds.³³

The improvement in the financial environment did not stop the pressures for a better offer; but it did pave the way for the government to finally launch the swap, practically without introducing any change to the proposal announced in June 2004. To put pressure on the bondholders, the government mentioned that it would be satisfied with a 50% level of acceptance and warned the bondholders that they would not be another offer.³⁴

The swap started on January 14, 2005. As minister Lavagna said, “it has come the moment for the markets to talk”. Six weeks later the restructuring operation was closed. On May 3, 2005, the government announced that the acceptance had reached 76.15% of the debt in default. This meant that 62.3 billion dollars of the old bonds would be exchanged for about 35.3 billion dollars of new instruments plus the corresponding GDP growth-linked coupons. The maximum amount of the issuing would be 15 billion dollars in the case of the Par bonds, 8.33 billion dollars in the case of the cuasi-Par bonds and about 11.9 billion dollars in the case of the Discount bonds.

The government expressed satisfaction at the swaps outcome. The operation signified the reduction in the public debt stock by about 67.3 billion dollars³⁵ and attenuated the public finances’ exposure to the exchange risk, since around 44% of the new bonds are denominated in local currency.

5. Argentina, the IMF and the international financial system

5.1. Argentina and the IMF, between the crisis and the swap

As we mentioned above, it is at first sight striking that the crisis and the massive default took place in a country that for a long time was considered an example of the Washington Consensus success. Almost until the end of the nineties, the IMF and most of the financial market’s analysts considered the Argentinean experience as one of the success stories of macroeconomic policy and structural reforms in the financial globalization context.

The default in Argentina took place one year after the IMF gave considerable support to sustain the convertibility program in crisis. In August 2001, four months before the default, the IMF expanded by 8 billion dollars the current stand by program and made a disbursement. At that moment the crisis was at its peak. The devaluation and default were openly discussed

³³ Some financial analysts opined that lower discount rates should be used, since after the restructuring, the Argentinean debt would turn out to be less risky than many of the countries’ debts used as a benchmark for the calculation.

³⁴ Moreover, aiming at relieving itself from the creditors’ pressures, the government resigned to the right of changing the guidelines of the proposal, by sending a bill to the Congress –quickly approved- that prevented the administration from doing it. The Congress should approve any further modification.

³⁵ According to the figures announced by the minister Lavagna, not published yet, in the end of 2004 the debt amounted 191.2 billion dollars. With the achieved haircut the new debt stock would amounts 123.9 billion dollars. The public debt/GDP ratio would have passed from 113% to 72%.

(particularly in financial and academic settings in the United States) and there was a widespread opinion that the debt and the convertibility regime were not sustainable.

Assistance to Argentina was the last rescue package approved by the IMF during the period of the Democrat's administration in the United States. All of the circumstances converged to make it an exemplary case for the critics of the IMF administration.

The program openly showed weak flanks susceptible to criticism from its very conception. It did not involve any substantial change in the current macroeconomic policy. In particular, the exchange rate regime was preserved. Besides the undeniable complexity and the difficulties that a regime change would have implicated, there was a complete lack of willingness to modify it among the authorities. Furthermore, from the IMF's perspective, the preservation of the regime was consistent with the systematic support of the exchange rate regime that the organization had provided throughout the nineties. The Argentinean currency board regime was usually mentioned as an example of a feasible "corner solution" for the exchange rate policy in an emerging market country (Fischer, 2001).

The program aimed at recovering confidence through a commitment to fiscal austerity measures. The accomplishment of these measures was unlikely and its effects were doubtful. In the middle of the crisis the recession and the liquidity crunch made, to a great extent, endogenous the fiscal account deterioration. It was implausible that the issuing of fiscal signals would be sufficient to stop the critical trends. In brief, in the moment when the program was approved and even more so in August 2001—when the program was extended—there was good reason to think that the multilateral resources would end up funding payments to the private creditors and capital flights, without being able to stop the crisis and prevent the default. And that is exactly what happened. Certainly, some of the characteristics of the rescue packages that were in the center of its criticisms were clearly observable in the support given to Argentina.

After the changes in the head of the organization that followed the Republican take over of the US administration, the relationship of the IMF to Argentina was used as a significant example of the problems with the previous management. The issue was important enough to carry out a special investigation by the Independent Evaluation Office (IEO, 2004).

The relationship between the IMF and Argentina after the devaluation and the default is marked by that story in a curious way. Actually, the IMF's support was absent precisely when it would have been more necessary: in the period after the devaluation, when efforts to stabilize the economy were at the center of the economic policy.

Although the new management's criticisms regarding the support given by the IMF to the convertibility regime were justified, this did not provide any reason for not supporting the post-devaluation stabilization efforts. On the contrary, the self-criticism of the IMF implies an acknowledgement of its own part of the responsibility for the crisis. Therefore, the organization should have been even more committed to the stabilization attempts.

With new authorities in both the institution and the country, at least a cooperative attitude by the organization might have been expected. Yet, the institution's orientation was precisely the opposite. The mentioning of “the mistakes that we made with Argentina in the past” helped to justify an extremely reticent attitude. The negotiations were centered in only one substantial matter: the Argentinean payments to the IMF.

The role the IMF played in the stabilization and the recovery of the economy in crisis was actually very negative. We have already mentioned, for example, its positions regarding the exchange rate policy. In February 2002, in a context of high political fragility, the IMF staff exerted pressures for the modification of the exchange rate policy adopted by the country after the exit of the convertibility regime (it was a fixed exchange rate system with controls on the purchases of international currency). This system was explicitly set up as a transitory one, intended to stabilize the nominal exchange rate while the domestic prices absorbed the impact of the devaluation. A flexible exchange rate would be established later. The IMF demanded the immediate pure flotation of the exchange rate, threatening to forgo negotiations with Argentina while the exchange controls were in place. As described in the previous sections, the measure demanded by the IMF was instrumented. It was followed by an abrupt rise in the price of the dollar, as it was clearly expectable, and a fast acceleration of inflation. The country got nothing in exchange for that “prior action.”

Soon after, the recently designated Minister Lavagna implemented a new stabilization program that preserved the flotation but instrumented interventions in the exchange market, and reinforced some exchange controls aiming at stabilizing the exchange rate. This policy also faced the opposition of the IMF, though in this situation the demands of the institution were not satisfied. The interventions and the control measures that were instrumented, in spite of the opposition of the Fund's staff, turned out to be crucial for the exchange rate and the inflation stabilization.

Another example of the negative role of the IMF is the orientation that it tried to impose on the bank crisis management. Since the Minister Lavagna took over, the government looked for a gradual exit from the crisis, favoring the generation of voluntary options for the savers and avoiding new shocks to the system. Confronting this orientation, the staff promoted heroic “solutions” with uncertain outcomes (banks liquidations, the restructuring of the public banks, etc.). This issue derived into an open conflict between the government and the Fund's staff that resulted in the creation of an arbitrating commission mainly compounded by European central bank's former presidents.

The government did not satisfy the main demands of the IMF regarding the management of the bank crisis. It persisted in its orientation, which ended up showing success when the exchange market stabilized and an incipient recovery of the economic activity helped to stabilize the savers' behavior. The crisis could be managed without ulterior disruptions in a context of gradual growth in bank deposits.

The two mentioned examples indicate that the Fund's staff operated in that phase with the diagnosis that the exchange market could not be stabilized, that a hyperinflationary process was

unavoidable and that it would be impossible to reestablish some degree of financial intermediation in domestic currency in the near future. The staff publicly acknowledged their diagnostic mistake later on. It is clear that had the economic policy followed the orientation that the IMF wanted, the evolution of the economy would have been more in line with what the IMF expected. The implementation of the measures promoted by the IMF would have transformed its implicit diagnosis in a self-fulfilling prophecy.

The IMF sustained a negative attitude towards Argentina for a long time. In the second semester of 2002 the exchange market and the prices stabilized, and the data of the activity level and the external sector performance started to show positive outcomes. The staff did not waste any occasion to make public its disbelief regarding the sustainability of the stabilization and the recovery of the activity and employment levels. In that matter, the public comment by the Deputy Manager Director Krueger is quite memorable, Deputy Krueger indicated that the recovery showed by the data was only “the bounce of a dead cat”. It wasn’t until May 2003 that the Deputy Manager Director publicly confessed to having failed in her diagnosis and manifested having been surprised by the quick economic recovery and by the fact that there was no hyperinflation.

The 2002 and 2003 agreements were signed in that high conflictive context in the relationship between the Argentinean government and the staff. Given the attitude of the latter, the political influences were crucial, specially the favorable position of the United States. In September 2003 a three-year agreement was subscribed, intended to refinance the amortizations of the debt with the institution. The refunding mechanism consisted in crediting new funds for the equivalent amount of the capital amortizations. This “fresh funding” was subjected to the usual terms of conditionality.

The terms of conditionality were established for the first year. The terms corresponding to the following two years were left to be defined in future negotiations. The most important of the committed targets was the magnitude of the consolidated fiscal primary surplus. A 3% of GDP was determined only for the first year of the agreement because the government resisted the pressure to commit increasing targets for the following years. Other important targets included in the agreement were the redefinition of the concessionaire contracts of public services and the establishment of new regulations on the public utilities (privatized in the nineties), the establishment of new measures tending to reinforce the financial system and the approval of a law about fiscal revenues distribution between the Nation and the provincial governments. The conditionality also included a clause under which the country committed good faith in the treatment of the external creditors. The ambiguity of the term left the IMF a great margin of discretion in the evaluation of the accomplishment of this clause.

One year later Argentina had comfortably fulfilled its quantitative fiscal and monetary targets, but not the qualitative conditions. Probably, the most significant target not fulfilled was the finalization of the renegotiation of the contracts and the establishment of a new regulatory frame for the privatized public utilities.

In the moment that the IMF had to evaluate the fulfillment of the conditionality clauses the country was presenting the debt restructuring proposal and organizing the swap. The relationship between Argentina and the Fund then reached an impasse, which foundations we comment next.

The IMF could have terminated the agreement, justifying the decision by the non fulfillment of the qualitative targets or by resolving that Argentina did not negotiate in good faith with the creditors. That would have signified a serious negative shock for a country in the middle of the debt restructuring process. Nevertheless, in those circumstances, the IMF would have also placed itself in a difficult position. Argentina still was one of the big debtors of the institution and there was a chance that the country would stop giving seniority to the multilateral debt and suspend payments. This would have generated a complex international problem. Furthermore, the interpretation that the IMF was interfering in the country's negotiation with the bondholders could have not been avoided, in contradiction with the doctrine saying that these matters should be solved by the parties involved without the IMF's intervention—this argument was particularly emphasized by the United States.

The impasse was overcome through the suspension of the program. Following a request from Argentina, the program was suspended until the beginning of 2005. Since the suspension Argentina has paid to the Fund all the interests and the amortizations that could not technically be postponed. They have also asked for and obtained the postponement of the payments that did have this possibility. Moreover, some minor capital payments were made which postponement could have been required. The Argentinean government did so to avoid the board's discussion of the Argentinean case before the swap was finished. In the period 2002-2004 the country made net capital payments to the IMF for more than 2.1 billion dollars, together with another 1.9 billion dollars in interests.

5.2. The United States position

The debt restructuring took place in the context of a conflictive relationship between the IMF and the country in question. This represented a new situation in the role played by the IMF in the international financial system. The most unusual feature is that the design and management of the debt restructuring were developed without the intervention of the IMF. This has no precedent in the international financial system constituted since the seventies. The importance of this novelty is highlighted both by the record dimension of the restructured debt and the unprecedented haircut—one of the highest in the history of debt restructuring in the recent globalization period.

The position adopted by the United States government was a crucial element in the process. Throughout its public manifestations and mainly throughout its influence in the IMF, it opened space for the development of the Argentinean strategy. This political attitude had its foundation in the orientation of the American government with respect the international financial system.

The American administration expressed the view that the crises and defaults result from excessive debts attributed to the irresponsible behavior of both the country and its lenders. This irresponsible behavior was encouraged in the past by the implicit guaranty given by the IMF's

rescue packages. We have already mentioned that the relationship between Argentina and the IMF, before the default, was a prominent example of those criticisms.

The United States demands less intervention of the IMF in the relations between the countries and their private lenders, both under normal conditions and in a default situation. The rejection by the United States of the Sovereign Debt Restructuring Mechanism initiative constituted a well-defined expression of that orientation.

The Argentinean government coordinated its discourse with this vision. It also mentioned the shared responsibility of the lenders and requested no intervention of the IMF, basing this last demand in the fact that the restructuring proposal did not involve additional multilateral funding. The long-term financial program on which the proposal was based did not assume additional multilateral funding in the future. The magnitude of the haircut in part derived from this characteristic.

The high haircut did not put the United States government in an uncomfortable position as it was presented as a particular feature of an exceptional case. The haircut could be seen as proportional to the irresponsibility shown by the market. In this special case the penalty would not be excessive. It seems to be consistent that the penalty happened to be exemplary tough in a case that became an example of irresponsible behavior by the country, its lenders and the IMF.

For the above-mentioned reasons, the Argentinean strategy did not conflict with the rhetoric of the United States government. On the contrary, throughout its different stages from 2001 on, the country has played an exemplary role for the United States orientation towards the international financial system, since it illustrated both the system flaws and the viability of alternative ways to solve its problems. The United States opened space for the implementation of the Argentinean restructuring strategy because the case could provide support to the idea that the countries and the markets can get around on their own, without the coordination and funds of the multilateral organizations. The high level of acceptance of the swap reinforces that idea.

5.3. Argentina and the IMF after the successful swap

After the debt swap, Argentina restarted the negotiations with the IMF with the asset of a high proportion of acceptance of the swap. The figure was not only relevant because it legitimized the operation. New actors and elements emerged after the episode such as the new bonds' quotations and the voices of the financial markets. After the swap Argentina brought to its side an important number of bondholders interested in a cooperative attitude of the IMF contributing to improve the new bonds' market valuation.

However, the IMF faced the Argentinean requirement from the point of view of its institutional logic. In this logic, the refinancing of the country's debt involved the approval of new loans. Actually, the purpose of these loans would have been to provide support to a fiscal financial program based on an autonomous strategic decision of the Argentinean government in which the IMF has not had any participation. Consequently, the acceptance of the Argentinean demand would have meant that the IMF was forced to accept an important innovation.

The conflicts involved in the treatment of the Argentinean case were exacerbated by the special circumstances that the institution is going through.

The role that the IMF played in the Argentinean sovereign debt restructuring was in the antipodes of the crucial role delineated in the initiative proposed by Anne Krueger at the beginning of her mandate.

From the beginning of the eighties the IMF actively participated in the restructurings of sovereign debts with the private sector. Regarding this tradition, the SDRM initiative seems to have been an attempt to precise, formalize and strengthen the mentioned function of the IMF. As we have already pointed out, after Wall Street and the United States government rejected the SDRM initiative, the role of the institution in cases of sovereign debt default remained undefined. The US government rejection not only frustrated the IMF initiative but also ended up questioning the very participation of the IMF and the commitment of multilateral funds in the restructuring of debts with the private sector.

Nowadays, the functions of the IMF in the international financial system are probably more undefined than ever before and the institution lacks of precise orientation. No new function replaced the role of “financial globalization central bank” to which its performance got close in the nineties. On the other hand, as we have already mentioned, the burial of the SDRM initiative was a hard negative shock to the aspiration of a new role for the institution, and nothing came in replacement.

From the point of view of its objectives as a multilateral financial institution, there is no doubt that the IMF should have given positive answers to the country’s demands and contribute to its normalization. However, from the point of view of the institution as a bureaucratic organization with its own interests, the agreement with Argentina implied the formal acknowledgement of a much less important role than the one played in the past.

Thus, the difficult negotiations that the country and the IMF maintained throughout the rest of 2005, after the debt swap, did not arrive to a new agreement. The government resolved to keep paying all the interests and the amortizations that could not technically be postponed during that year, to finally adopt the decision to cancel all obligations with the institution, as it was done at the beginning of 2006.

It frequently happened that the developed countries governments –with the particular influence of the United States- redefined the functions of the IMF while trying to deal with immediate and specific problems. That happened, for example, in 1982, when a new function for the IMF in the negotiations of defaulted external debts was defined, after the Mexican case. Something similar happened in 1995, also after a Mexican crisis, when the rescue packages policy for dealing with capital account crises was instituted.

Under the light of the aforementioned tradition, the Argentinean case may be indicating a lasting redefinition of the functions of the IMF in the international financial system.

Table 4
Comparison between average public deficit of 1998-2001 and 1994
(in millions of dollars)

Consolidated deficit variation	7,112
Social Security deficit variation	4,867
National Administration's primary deficit variation (excluding Social Security)	-5,131
Provincial primary deficit variation	592
Consolidated interest payment variation	6,784

Source: Authors' calculations based on Ministry of Economy and Cetrángolo et al. (2000)

Table 5
Total public interest payments, Tax collection-GDP ratio and sovereign risk premium
(in percentage)

Year	Tax collection as percentage of GDP (1)	Average interest rate on public debt (2)	Interest payments / tax collection ratio (3)	Sovereign risk premium (annual average)
1991	18.8	s.d	5.5	9.6
1992	20.8	6.6	8.3	6.9
1993	21.3	5.0	6.0	4.9
1994	21.1	5.5	6.9	5.9
1995	20.9	6.1	9.2	12.4
1996	19.6	5.8	9.7	6.5
1997	21.0	6.7	10.9	3.3
1998	21.4	7.6	12.2	5.8
1999	21.4	8.3	15.9	7.2
2000	21.9	8.9	18.5	11.5
2001	21.0	9.4	23.4	14.8
2002	19.2	5.2	13.3	.-
2003	23.1	1.9	9.6	.-

(1) Includes Security System receipts.

(2) Calculated as a ratio between interest payment in period t and debt at the end of t-1.

(3) Tax receipts include those from social security system.

Annex

Table 8
Evolution of the Gross Public Debt (National Government),
(since December 31st 2001 to December 31st 2003, in Million Dollars)

Item	Amount	(1)	(2)
I. Total Debt Stock (December 31st 2001)	144,45	466	53.8
II. "Forced and inertial" debt increases resulting from the breakdown of the convertibility regime (1+ 2 + 3)	28,184		
1. Debt emission as from December 2001	28,525		
To alliviate financial system distress	14,390		
To compensate the banks for the asymmetric pesification	5,904		
To cover banks' currency mismatch	2,400		
To domestic savers	6,086		
To assist Provinces	12,108		
Povincial Warranted Bonds (BÖGAR)	9,679		
To rescue provincial quasi-moneys	2,429		
To cancel obligations with public workers, suppliers, and others	2,028		
To give back a 13% wage cut to public workers	873		
Consolidation Bonds (Bocones given to suppliers, etc.)	1,155		
2. Effects of pesification, inflation adjustment (CER) and others	-14,284		
Debt reduction through pesification	-22,086		
Debt increases because of inflation adjustments (CER)	7,325		
Adjustment of Global Bond with Dollar conversion clause	477		
3. Interest Arrears as to December 31st 2003	13,943		
Unpaid interests	9,974		
Capitalized interests	3,969		
III. Amortization, effects of exchange rates' variations and others	6,183		
Debt amortization	-5,411		
Debt reduction through capital net payments to IFI's	-3,340		
Debt reduction through other amortizations	-2,071		
Net Central Bank Credit to the National Government	2,851		
Effects of exchange rates' variations and others	8,743		
Total Debt increases between December 31st 2001 and December 31st 2003	34,367		
IV. Total Debt Stock (December 31st 2003)	178,820	533	146.0

Table 10
Characteristics of New GDP-linked Units

Reference Amount	GDP-linked units will be issued in respect of the principal amount of bonds tendered for exchange
Calculation currency	Peso
Payment currency	U\$\$, Euro, Yen, Peso
Maturity	30 years
Calculation date	Annually on November 1, commencing in 2006
Payment date	Annually on December 15, commencing in 2006
Payment Amount	5% of excess GDP divided by the average free market exchange rate of pesos per U.S. dollar, euro or yen, during the 15 days preceding the payment date
Payment trigger	Actual GDP (expressed in constant pesos) as of the reference date exceeds the base case GDP, and the annual growth rate exceeds 3%
Maximun Payment Amount	The GDP-linked Securities no longer be entitled to any payments if the total amount paid, during its life, per unit of GDP-linked Security exceeds 0.48. This amount will be referred as the “payment cap for GDP-linked Securities.”
Base case GDP	Projected real GDP from December 31, 2004, at an approximate annual growth rate of 3%
